(Accepted 30 April 1993)

Forty-three species have been assigned to *Pilodius*. This revision accepts 12 and, in addition, establishes three new species. These 15 species are described, figured, and their distributions mapped. A key to the genus is provided.

KEYWORDS: Crustacea, Xanthoidea, Brachyura, *Pilodius*, identification key, taxonomy, new species.

Introduction

Alphonse Milne Edwards (1873), Balss (1938a), Serène and Luom (1958, 1959), Forest and Guinot (1961) and Serène (1984) (Table 1) have all attempted revisionary studies of *Pilodius* Dana, 1851, but none of these authors completely unravelled the complex taxonomic problems associated with this taxon. The independent description of *Pilodius* under the name *Chlorodopsis* by A. Milne Edwards created chaos within the Chlorodiinae that was only resolved when Forest and Guinot (1961: 90) applied the rule of priority. In the period between Dana establishing *Pilodius* and Forest and Guinot finally imposing nominal stability, > 30 species were assigned to the *Pilodius*/*Chlorodopsis* complex. In fact, to date, a total of 43 (Table 2) species have been attributed to this group. This revision retains only 12 (Table 3), and in addition describes three new species.

Abbreviations

AM, Australian Museum, Sydney; AMNH, American Museum of Natural History, New York; BBM, Bernice Bishop Museum, Honolulu; IRSNB, Institut Royal des Sciences Naturelles de Belgique; MI, Mauritius Institute; MNHN, Muséum national d'Histoire naturelle, Paris; NHM, The Natural History Museum, London; NUS, National University of Singapore; OINT, Oceanographic Institute, Nha Trang, Vietnam; QM, Queensland Museum, Brisbane; SAM, South African Museum; SMF, Senckenberg Museum, Frankfurt-am-Main; SWU, Shikoku Women's University, Japan; USNM, United States National Museum, Smithsonian Institution; UMZC, University Museum of Zoology, Cambridge; UY, University of York; ZLKU, Zoological Laboratory, Kyushu University, Japan; ZSI, Zoological Survey of India.

The zones of the carapace are divided according to Serène (1984: 18) and all measurements refer to the width of the carapace.

Description

Carapace depressed, transversely oval, regions defined. Front, hardly projecting, more than one-third carapace width; margin divided into two large submedian lobes and two small lateral lobes. Anterolateral margins tri- or quadridentate, equal to or shorter than markedly convergent posterolateral margins. Posterior margin costate, short. Antennule fosset transverse. Basal antennal segment in adult butting into orbital hiatus, excluding short, slender antennal flagellum from orbit. Anterior margin of buccal cavity well defined, covered by third maxillipeds; exhalent channels faintly indicated on posterior region of palate only. Exopod of third maxilliped, shorter than endopod, columnar, distally notched, bearing triangular tooth distally on inner margin. Lateral margins of endopod ischium nearly parallel, proximal margin obliquely truncate, oblique shallow sulcus near setose internal margin; inner distal angle of merus excavate; carpus setose distally on dorsal surface and propodus with setal tuft, dactylus terminally setose. Chelipeds unequal, fingers massive, spoon-shaped. Superior margin of pereiopods spinulate or tuberculate, external surface of pereiopodal carpi furrowed. Modifications of dactylo-propodal articulation well defined, dactylus tip cornute. Genital openings coxal. Male with 5 abdominal segments.

Remarks

Dana (1851: 125) initially established *Pilodius* as a genus within the Chlorodinae and then (1852: 80) treated it as a subgenus of *Chlorodius* Leach. In the same publication he also assigned *Chlorodius pilumnoides* White to *Pilodius* and described four new species (see Table 1). Later, Dana (1853: 216) returned the taxon to generic status. Alphonse Milne Edwards (1873: 227) described *Chlorodopsis*, to which he attributed three species and described two new ones (Table 1). Bouvier (1915: 99) stated that *Chlorodopsis* was different from other 'chlorodiens' such as *Pilodius*, *Chlorodius*, *Phymodius* A. Milne Edwards and *Xanthodes* Dana, a view supported by Balss (1934: 227). Ward (1932: 250) also considered *Chlorodopsis* valid and subsequently named

Table 2. A list of the 43 species that have been assigned to the *Pilodius* complex.

C. melanochirus A. Milne Edwards as the type species. In an attempt to clarify the situation Balss (1938a: 56, 58) assigned six species to *Pilodius* and five to *Chlorodopsis* (Table 1). Serène and Luom (Table 1) extensively revised *Chlorodopsis*. In their generic discussion they considered (1959: 333) *Chlorodopsis* and *Pilodius* to be synonymous and recommended that the nomenclatorial confusion should be rectified by applying the rules of priority in favour of *Pilodius*. But in their concluding comments (p. 336) they ignored their own suggestion and adopted the junior synonym *Chlorodopsis*. They reasoned that the name *Pilodius* should be abandoned because its definition was insufficient and, therefore, the less ambiguous description of *Chlorodopsis* by A. Milne Edwards should be used. Forest and Guinot (1961: 90) opposed the decision made by Serène and Luom because, in their opinion, the definition of *Pilodius* by Dana was adequate, and it was incorrect to propose derogation of the law of priority by utilization of the name *Chlorodopsis*. Dana did not select a type species for *Pilodius*, so Forest and Guinot subsequently designated *Chlorodopsis pilumnoides* White, 1848 as the type species. Forest and Guinot (1961: 89) listed the species assigned to *Pilodius* Dana, 1852 under their original names (Table 1).

Of the 43 species listed (Table 2), eight were misidentified, and a further six were assigned to other genera within the subfamily Chlorodiinae because the original description of *Pilodius* by Dana 1852 was inadequate. On the basis of this description, Serène (1984: 233) suggested that the exclusion of the antennal flagellum from the orbital hiatus by the prolongation of the basal antennal segment is a character for separating *Pilodius* from other genera of the Chlorodiinae. However, Crosnier pointed out (footnote, Serène 1984: 233) that this prolongation develops with age and may not be useful for identifying juveniles. Furthermore, Crosnier noted that some species of *Pilodius*, i.e. *P. paumotensis* Rathbun, have only a very feeble prolongation, even in mature specimens, whereas species of other genera, such as *Phymodius unguilatus* H. Milne Edwards, can have a slight prolongation of the basal antennal segment. Despite this limitation the prolongation of the basal antennal segment remains the sole character for distinguishing *Pilodius* from other Chlorodiinae.

Type status

The type of the genus is *Pilodius pilumnoides*, and the specimens are extant in The Natural History Museum. Gender masculine.

Phymodius unguilatus: Boone, 1934: 143 (part); Serène and Luom, 1958: 96; Serène, 1984: 241. non H. Milne Edwards, 1834.

Description

Regions of carapace well defined, separated by deep grooves, 2M divided into two longitudinally, 3M tripartite, anterior lobe not reaching anterior margin of 2M, densely covered with minute setae, leaving free only pearliform granules. Submedian frontal lobes arched, minutely denticulate, separated by 'U'-shaped indentation, lateral lobes triangular, granulate. Anterolateral margin quadrilobate, lobes rounded, granulate. Anterior margin of cheliped merus granulate. External surface of cheliped carpus with clusters of pearliform granules, one furrow parallel with palmar joint. External surface of chela minutely setose, proximally set with large rounded granules, lower margin smooth. Pereiopods thickly fringed with plumose setae; merus, carpus with conical tubercles on superior margin; carpus, propodus with pearliform granules externally.

Temae, 17°29'S, 149°46'W, Polynesia; coll. H. G. Müller, 31/iii/1988, 0–0.5 m; 5♂ 18–11 mm, 3♀ 16–12 mm, 2 juvs (SMF no reg.).

Viti Levu Is., Fiji; 1♂ 24 mm, 1♀ 20 mm (SMF 1711) (Ex. Museum Godeffroy). Rotuma Is., Fiji; coll. J. S. Gardiner; 1♂ 14 mm, 1♀ ovig. 11 mm, 4♀ 15.5–11 mm; formerly *Actaea affinis* det. L. A. Borradaile, redet. T. Odhner 1922 as *Chlorodopsis areolatus* (UMZC Sept. 15, 1897).

Remarks

Crabs identified by Borradaile (1900) and Rathbun (1907, 1911, 1914) as *Actaea affinis* and deposited in the University Museum of Zoology, Cambridge were redetermined as *Pilodius areolatus* by T. Odhner. Miers (1886: 135) erroneously synonymized the *Actaeodes affinis* Dana (1853: 197) with *Actaeodes tomentosus* (H. Milne Edwards), see Montgomery (1931). A number of species are considered junior synonyms of *Pilodius areolatus*, *Xantho dehaanii* Krauss by Miers (1884), *Chlorodius perlatus* MacLeay by A. Milne Edwards (1873), *Etidodes caelatus* Dana by Haswell (1882), *Actaeodes affinis* Dana (assigned to *Actea* by A. Milne Edwards) by Montgomery (1931) and *Actea perlatus* and *Chlorodopsis areolatus brandonensis* both of Ward by Barnard (1950). The *Chlorodius areolatus* material of Adams and White (1849) was assigned by A. Milne Edwards (1873: 232) to *Phymodius unguilatus*, however, this material was examined during this revision and the identification of Adams and White was confirmed.

Distribution

Reported from the Red Sea and east coast of Africa to Mangareva, Polynesia, Pacific Ocean (Fig. 16).

Type status

The Type from Nouvelle-Hollande (Australia) is no longer extant.

Pilodius cephalalgicus sp. n.

(Figs 2A–G, 31B, 40B)

Description

HOLOTYPE male. Regions of carapace well defined, 2M divided into two longitudinally, areoles granular, granules acuminate, apically cornute on 1L–5L, set with short, coarse, dark setae. Transverse row of adjoining pearliform granules medially on 1P; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes arched, prominently denticulate, separated by deep ‘U’-shaped indentation, lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth multispinose, apically cornute, terminal spine accompanied by ancillary spines. Anterior margin of cheliped merus prominently spinose. External surface of cheliped carpus with cornute, conical tubercles, coarsely setose, ill-defined furrow parallel with palmar joint. External surface of chela set with short, coarse, dark setae; cornute, conical tubercles on upper margin, rounder inferiorly; lower margin granulate and dark coloration restricted to fixed finger. Pereiopods with coarse dark setae, merus, carpus prominently spinose on superior margin.

Material examined

Malayan Peninsula

Sta. 20, 6°55'N, 102°45'E; coll. Serène, 24 July 1965; 1♂ 20 mm, HOLOTYPE (MNHN MP B.20935)—4♂ 14–10 mm, 1♀ 11 mm, PARATYPES (MNHN MP B.24030)—Sta. 15, Tilok Kekhe, Perhentian Besar, 6°55'N, 102°45'E; 21 July 1965, 1♂ 8 mm, PARATYPE (MNHN MP B.24031)—1♂ 10 mm, 1 juv., PARATYPES (MNHN MP B.24029)—1 juv., PARATYPE (MNHN MP B.24034)—Sta. 18, 6°55'N, 102°45'E; 23 July 1965; 1♂ 8 mm, PARATYPE (MNHN MP B.24032)—Sta. 31, Poulo Babi Nyong, 2°30'N, 103°57'E; 21 August 1965; 1♂ 16 mm, PARATYPE (MNHN MP B.20936).

Remarks

Pilodius cephalalgicus sp. n. is morphologically similar to *P. pilumnoides*, because the anterior margin of the cheliped merus is spinose, but it differs from the latter by the dark coloration on the cheliped being restricted to the fixed finger. The pleopods of these two species are distinct.

Distribution

Restricted to the east coast of the Malayan Peninsula (Fig. 17).

Type status

Type series extant and deposited in the Muséum national d'Histoire naturelle, Paris. Holotype from 6°55'N, 102°55'E, Malayan Peninsula.

Etymology

Cephalalgicus from the Greek Kephalalgikos, meaning causing a headache, referring to the severe taxonomic problems the authors encountered while revising *Pilodius*. Gender masculine.

Pilodius concors sp. n.

(Figs 3A–G, 32A, 40C)

Chlorodopsis pilumnoides: Balss, 1938b: 56; Tweedie, 1950a: 92; Guinot, 1958: 179, fig. 25a, b. **non** White, 1848.

Pilodius nigrocrinitus: McNeill, 1968: 73 (part). **non** Stimpson, 1859.

Description

HOLOTYPE male. Regions of carapace well defined, 2M divided into two longitudinally. Areoles prominently granular, set with short coarse setae; on 1L–5L granules larger, apically cornute. Transverse row of adjoining pearliform granules on 1P; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes arched, prominently denticulate, separated by deep 'U'-shaped indentation, lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth multispinose, apically cornute, terminal spine accompanied by ancillary spines. Anterior margin of cheliped merus prominently spinose. External surface of cheliped carpus with large cornute tubercles, coarsely setose, furrow parallel with palmar joint. Upper margin of chela with cornute tubercles, external surface smooth. Pereiopods with coarse dark setae, merus, carpus, propodus prominently spinose on superior margin.

Material examined

Australia

Hock Reef, East of Hayman Is., Queensland; coll. F. A. McNeill and J. K. Howard, May 1953; 1♂ 37 mm, PARATYPE (AM P. 12306). Great Barrier Reef, Queensland; coll. Great Barrier Reef Expedition 1928–29; 1♂ 18 mm, PARATYPE; formerly det. F. A. McNeill *Pilodius nigrocrinitus* (NHM 1937.9.21.104–123). Cape York, Queensland; 1♂ 25.5 mm, PARATYPE; was reg. 319.68 (MNHN MP B.2394). Coconut Beach, west side of Lindeman Is.; Queensland; coll. P. Davie and J. Short, 26 March 1987, 16 m; 1♂ 22.5 mm, PARATYPE (QM W.12914) (part).

Southeast Asia

Pulo Condore; coll. Mr Germain (410–68); 1♂ 19 mm, PARATYPE; formerly det. D. Guinot *Pilodius pilumnoides* (MNHN MP B.13755). Horsburgh Lighthouse, Singapore, South China Sea; coll. A. Monteiro, April 1938; 1♂ 62 mm, HOLOTYPE; formerly det. Tweedie *Chlorodopsis pilumnoides* (NUS 1965.11.11.147)—Sultan Shoal; coll. M. W. F. Tweedie, December 1933; 1♀ 61 mm, PARATYPE (NUS 1965.11.11.149)—Sentosa Reef; coll. P. K. L. Ng, 13 December 1989; 2♂ 44–37.5 mm, 1♀ 32.5 mm, PARATYPES (NUS 1989.3428–3430). Tekek Bay, Pulau Tioman, Malaysia; coll. P. K. L. Ng, June 1983; 1♂ 58 mm, PARATYPE (NUS 1985.1506).

Edam Is. (Damar Besar), Djakarta, Java, Indonesia; coll. J. Brock; 2♂ 23–21 mm, PARATYPES; formerly det. De Man as *Ch. melanochira*; Ex. Museum Göttingen (SMF 592a) (part).

Remarks

Specimens referred to by Balss (1938b), Tweedie (1950a) and Guinot (1958) as *P. pilumnoides*, and by McNeill (1968) as *P. nigrocrinitus* (part) pertain to *P. concors* sp. n. *Pilodius concors* sp. n. is morphologically similar to *P. maotieni*, *P. cephalalginicus* sp. n. and *P. pilumnoides* in having 1L–5L with conical tubercles, but it differs from these species by having the lower external surface of the cheliped smooth. The pleopods can also be used to separate these species.

Etymology

From the Latin *concors*, to be of one mind, for the authors' decade of scientific cooperation. Gender masculine.

Distribution

Off the southern coast of Vietnam (South China Sea) to the northwest coast of Queensland, Australia (Fig. 18).

Type status

Type series extant and the holotype is deposited in the National University of Singapore. Type locality is Horsburgh Lighthouse, Singapore, South China Sea.

Pilodius flavus Rathbun, 1894

Chlorodopsis pilumnoides: Laurie, 1906: 406. **non** White, 1848.

Chlorodopsis hawaiiensis Edmondson, 1962: 273, fig. 21a–e.

Description

Regions of carapace well defined, 2M partly divided into two longitudinally, granulose, granules conical, prominent laterally, dorsal surface covered with long bristly setae. Two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes broad, denticulate, separated by 'U'-shaped emargination, lateral lobes small, bluntly triangular. Extraorbital angle prominently spinose. Anterolateral margin quadridentate, teeth distinct, spinose, second and third teeth often with ancillary spines. Anterior margin of cheliped merus spinose. External surface of cheliped carpus with long conical tubercles, setose. External surface of chela with large tubercles, conical near upper margin, rounder medially, lower margin smooth. Pereiopods with long bristly setae, merus, carpus, propodus with produced slender spines on superior margin.

Remarks

Rathbun (1911) noted that *Chlorodopsis melanospinis* resembled *Pilodius flavus*, but its carapace was not as deeply areolated and devoid of spines on the dorsum and upper margin of the orbit. In contrast, Serène (1984) regarded the differences in areolation as difficult to appreciate, but the presence or absence of spines on the orbital margin as providing a good character for differentiation. He further commented that for the males of these two species the pleopods were of the same type (Serène and Luom, 1959: fig. 2c, m). A study of the male chelipeds by Serène led him to conclude that the black coloration extends further back on to the propodus in the case of *P. flavus*, but not all in the case of *Ch. melanospinis*. After examination of *Pilodius flavus* and *Chlorodopsis melanospinis* specimens, we regard them as one species. We agree with some of the observations made by Serène, i.e. that differences in areolation are not significant and that pleopod morphology is identical, but after examination of a large number of specimens the difference in the spinulation of the orbital margin as originally described by Rathbun appears to be just variation. Furthermore, the coloration of the male chelipeds is the same in both species, with the larger cheliped of the male appearing to develop in specimens > 12 mm carapace width. The *P. pubescens* of De Man (1902) were deposited in Senckenberg Museum and were examined by Balss (1938a), who redetermined them as *P. flavus*. Balss (1938a) also considered the material that Nobili (1907) tentatively identified as ?*P. pubescens* as *P. flavus*. During this study, material identified by Edmondson (1962) as *Chlorodopsis hawaiiensis* was examined and proved to be *P. flavus*.

Distribution

From Aldabra Is., Indian Ocean to Hawaiian Is., Pacific Ocean (Fig. 19). Not recorded from the coast of east Africa or the Red Sea.

Type status

Holotype is extant, see material examined, United States National Museum, Smithsonian Institution. Type locality, off Sandwich Is. (Hawaii), 21°14'51"N, 157°43'30"W.

Description

Regions of carapace well defined, separated by wide, smooth grooves, areoles granular, set with tufts of setae. 2M divided into two longitudinally. 1P uniformly granulate; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes rounded, denticulate, separated by 'V'-shaped emargination, lateral lobes triangular, denticulate. Anterolateral margin quadrispinose, teeth multispinose. Anterior margin of cheliped merus tuberculate. External surface of cheliped carpus with large tubercles, minutely setose, wide furrow parallel with palmar joint. External surface of chela with large tubercles, conical near upper margin, rounder medially, lower margin smooth. Pereiopods setose, merus, carpus distinctly spinose on superior margin.

No locality; 1♂ 11 mm (SMF 7131).

Remarks

Stimpson (1859: 34) described this species only briefly, without reference to a figure. Miers (1884: 216) identified Stimpson's species as *Chlorodopsis granulatus* from material collected in Singapore and Australia, and gave a full description of the male specimen from Port Molle (no. 95), Australia, which was figured (plate XXI fig. A, a). After the death of Stimpson in 1872, his report on the Crustacea (Brachyura and Anomura) collected by the North Pacific Exploring Expedition 1853–56, was discovered and Rathbun, realizing the importance of the historical document,

published the manuscript (Stimpson, 1907). In this paper Stimpson gave an extended description of *P. granulatus* and figured (plate VII, fig. 2) the type from Hong Kong Is. The male cheliped coloration figured and described by Stimpson differs from that of Miers, and this has caused much confusion. Stimpson (1907: 59) described the male cheliped of *P. granulatus* as possessing a broad encircling band of brown near the bases of the fingers. His figure does not show this brown band present on the dorsal margin of the propodus, i.e. the coloration does not circumvent the palm of the cheliped. Miers described cheliped colour variation in the HMS *Alert* material collected by R. W. Coppinger from Australia. The cheliped of the male from Port Molle (no. 95) had fingers coloured deep brown, and this coloration extended over the greater part of the inner and outer surfaces of the palm (see Miers, plate XXI, fig. a). The coloration encompasses the palm of the male cheliped. This type of cheliped was exhibited by another male from Port Molle (no. 103). Miers further described a male from Port Darwin as a variety (see plate XXI, fig. a'). Re-examination of this specimen revealed that the faded coloration pattern of the cheliped propodus was identical to that of *P. granulatus* Stimpson, 1859. The HMS *Alert* material from Australia consists of two species, *P. granulatus* Stimpson and a new species, subsequently described by Ward (1936: 4) as *P. miersi*. In the reference collection of the National University of Singapore are type specimens attributed to *Pilodius sakitensis* by Serène. However, this name appears only in a manuscript found by Crosnier, Paris Museum, and the type material is here ascribed to *P. granulatus*. Specimens of *Chlorodopsis philippinensis* Ward (1941), *Pilodius philippinensis* Serène (1971) and *P. serenei* Miyake and Takeda (1968) were examined during this present study and all are identified as *P. granulatus*.

Distribution

From Hong Kong and Singapore to the east coast of Queensland, Australia (Fig. 20).

Type status

The Type of *Pilodius granulatus* Stimpson is no longer extant (Manning, personal communication), it was destroyed in the Chicago fire of 1871. Type locality Hong Kong.

Pilodius maotieni Serène, 1971

(Figs 6A–G, 33B, 41C)

Chlorodopsis pilumnoides: Serène and Luom, 1958: 102 (part), pl. IC, IIIa, IVB; 1959: 302 (part), fig. 2A, 5G, pl. 3A. **non** White, 1848.

Pilodius maotieni Serène, 1971: 913; 1984: 238, fig. 152.

Description

Regions of carapace well defined, separated by wide, smooth grooves. 2M divided into two longitudinally. Areoles granular, set with short, dark, coarse setae interspaced with longer, finer ones. On 1L–5L granules larger, conical, apically cornute. Transverse row of adjoining pearliform granules on 1P; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes rounded, denticulate, separated by 'V'-shaped emargination, lateral lobes triangular, denticulate. Anterolateral margin quadridenticulate, teeth multispinose. Anterior margin of cheliped merus tuberculate. External surface of cheliped carpus with dark conical tubercles, setose. External surface of chela with dark tubercles, large,

conical, well spaced near upper margin, smaller, rounder and closer set inferiorly. Lower margin smooth. Pereiopods setose, merus, carpus distinctly spinose on superior margin.

Material examined

Pilodius luomi Serène, 1971: 913, 1984: 240.

Description

Regions of carapace well defined, 2M divided into two longitudinally, 3M tripartite, anterior lobe surpassing anterior margin of 2M. Areoles with rounded granules, minutely setose. 1P uniformly granulate; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes arched, denticulate, denticles diminishing in size laterally, separated by 'U'-shaped emargination, lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth basally tuberculate, apical spine curved. Anterior margin of cheliped merus tuberculate. External surface of cheliped carpus with clustered granules, furrow parallel with palmar joint. External surface of chela with conical tubercles on upper margin, diminishing in size inferiorly, lower margin smooth. Pereiopods setose, merus, carpus with conical tubercles on superior margin.

Remarks

Miers (1884: 216) identified material from Australia, collected by HMS *Alert*, as *Chlorodopsis granulatus* (Stimpson). Examination of the specimens revealed the presence of two species, *Pilodius granulatus* Stimpson (plate XXI, fig. a') and a new species (plate XXI, fig. A, a), later described by Ward (1936: 4) as *P. miersi*. The cheliped figured by Miers (plate XXI, fig. A, a) features pigmentation that encompasses the propodus, and corresponds exactly with the type material of Ward (NHM reg. 1937.7.15.21–23, 1940.2.23.4) from Lindeman Is., Queensland, Australia. Figures by Sakai and by Serène and Luom under the name of *P. granulatus* are of *P. miersi*. *P. luomi* paratypes of Serène (1971: 913, 1984: 240) deposited in the National University of Singapore (reg. 1965.11.11.30–44) were examined and the pigmentation pattern of the male chelipeds matches the *P. miersi* of Ward. Further, Dai and Yang's illustration (1991: 328, pl. 43(3), fig. 165B.2) of the first pleopod and their description of the cheliped manus with a black circular band, pertain to *P. miersi* not to *P. granulatus*.

Distribution

Singapore eastwards to Queensland, Australia and Japan (Fig. 22). Not recorded from the Indian Ocean.

Type status

Type series is extant, see material examined in the Natural History Museum. Type specimens in the Australian Museum, Sydney were not examined. Type localities are cited as Singapore and Lindeman Is., Queensland, Australia.

Pilodius moranti sp. n. (Figs 8A-D; 34B, 42A)

Description

HOLOTYPE male. Regions of carapace well defined, 2M divided into two longitudinally, smooth furrows dividing setose granulose areoles, granules more prominent laterally. 1P uniformly granulate; sinuous transverse row of adjoining pearliform granules on 2P. Submedian frontal lobes arched, minutely denticulate, medially produced, separated by narrow sinus, lateral lobes triangular, granulate. Anterolateral

margin quadridentate, teeth multispinose, two median teeth wider, more prominent. Anterior margin of cheliped merus proximally tuberculate. External surface of cheliped carpus with two setae-fringed furrows parallel with palmar joint. External surface of chela closely set with conical tubercles, smaller, obsolescent inferiorly, lower margin smooth, longitudinal furrow proximally near upper margin. Pereiopods thickly fringed with long setae; merus, carpus prominently spinose on superior margin. Posterior surface of pereiopodal carpus medially with deep setae-fringed furrow, its borders granulate.

Etymology

This species is named for Harry Morant, Australian bushman, poet and soldier, who, in spite of being innocent, was executed during the Boer War in Pietersburg on 27 February 1902. Gender masculine.

Material examined

Australia

Wreck Reef, nr Porpoise Cay, Queensland; coll. J. Short and S. Mullens, 10 May 1988, 0.5 m; 1♂ 21 mm; PARATYPE (QM W. 15454)—14 May 1988; 4♂ 16.5–9 mm; PARATYPES (QM W. 15456)—2♀ 19–14 mm; PARATYPES (QM W. 15142)—1♂ 24 mm; PARATYPE (QM W. 15143)—0.5 m; 1♀ 22 mm; PARATYPE (QM W. 15455).

NE coast of Australia?; coll. Mr Rayner, Surgeon, HMS *Herald*; 1♂ 12.5 mm, 1♀ 13 mm; PARATYPES; purch. Mr Warwick (NHM 1862.53). Lord Howe Is., New South Wales; coll. P. R. Redley, April 1910; 1♂ 24 mm; HOLOTYPE (AM P. 2371)—coll. Icely, 1889; 1♂ 27.5 mm; PARATYPE (AM P. 366).

Middleton Reef, Tasman Sea; coll. J. Short and R. McKay, 9 May 1987; 1♀ 20 mm; PARATYPE (QM W. 13025)—1♀ 9 mm. PARATYPE (QM W. 13026).

Remarks

Pilodius moranti keys out as close to *P. granulatus* and *P. spinipes* in having 1L–5L lacking conical tubercles, but it differs from these two species because the carpus of the cheliped has two anterior furrows. These three species have distinct pleopods.

Distribution

Only recorded from the east coast of Queensland, Australia and the Tasman Sea. (Fig. 23).

Type status

Type series is extant and deposited in the Queensland Museum, Australia.

Pilodius nigrocrinitus Stimpson, 1859

non *Pilodius nigrocrinitus*: McNeill, 1968: 73 (part)=*P. concors* sp. n.

Description

Regions of carapace well defined, covered with coarse dark setae. 2M partly divided into two longitudinally, minutely granulate, granules more prominent laterally. 1P uniformly granulate; sinuous transverse row of adjoining pearliform granules on 2P. Submedian frontal lobes arched, minutely denticulate, separated by 'U'-shaped indentation; lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth multispinose, spines subequal, cornute. Anterior margin of cheliped merus tuberculate, tubercles diminishing in size distally. External surface of cheliped carpus coarsely setose, with cornute conical tubercles, lacking longitudinal furrow parallel with palmar joint. External surface of chela coarsely setose proximally, with conical tubercles proximally, smaller, obsolescent inferiorly, lower margin smooth. Pereiopods thickly fringed both with plumose setae and dark coarse setae, merus, carpus prominently tuberculate on superior margin.

Remarks

Stimpson (1859: 34) based his description of *P. nigrocrinitus* on a female, but this species was subsequently described and figured by A. Milne Edwards (1873: 117, pl. VIII, fig. 5) under the name *Chlorodopsis melanochirus*. A report written by Stimpson (1907) and published posthumously by Rathbun, included a figure (pl. VIIa, b) of the female holotype. This figure was used by Balss (1938: 57) to establish that *C. melanochirus* is a junior synonym of *P. nigrocrinitus*. Sakai (1939: 504, Text-fig. 42) illustrated the left pleopod of *P. nigrocrinitus* from its ventral aspect. The accuracy of this drawing was confirmed by Serène and Luom (1958, pl. IVe, 1959: 314, fig. 2B) who figured the ventral view of the right pleopod. The left pleopod of *C. melanochira* is figured in ventral aspect by Serène and Luom (1958, pl. IVd) and corresponds to that presented by Sakai (1939: 504, Text-fig. 42).

Distribution

Ranging from the eastern Indian Ocean (Andaman and Nicobar Is.) to Japan, the Society and Hawaiian Is. in the Pacific Ocean (Fig. 24). Not recorded west of longitude 90°E.

Type status

Stimpson based his description of *P. nigrocrinitus* on a female which is no longer extant because it was destroyed in the great fire of Chicago 1871. Type locality was Simoda, Japan.

Chlorodopsis pilumnoides: Barnard, 1955: 3 (part); Michel, 1964: 24; Guinot, 1967: 268 (part). **non** White, 1848.

Description

Regions of carapace nearly indistinct, dorsal surface shagreened, with short pubescence interspaced with long setae. 2M entire. 1P uniformly granulate; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes arched, minutely denticulate, separated by 'U'-shaped emargination; lateral lobes triangular, denticulate. Anterolateral quadridentate, two median teeth largest. Anterior margin of cheliped merus proximally tuberculate. External surface of cheliped carpus with furrow parallel with palmar joint. External surface of chela with short pubescence interspaced with long setae, tuberculate. Pereiopods setose, merus, carpus with conical tubercles on superior margin.

Description

Regions of carapace well defined, 2M divided into two longitudinally, areoles prominently granular, granules acuminate, apically cornute on 1L–5L, set with short, coarse, dark setae. Transverse row of adjoining pearliform granules medially on 1P; two parallel transverse rows of adjoining pearliform granules on 2P, anterior row medially disjunct. Submedian frontal lobes arched, prominently denticulate, separated by deep ‘U’-shaped indentation, lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth multispinose, apically cornute, terminal spine accompanied by ancillary spines. Anterior margin of cheliped merus prominently spinose. External surface of cheliped carpus with cornute, conical tubercles, coarsely setose, ill-defined furrow parallel with palmar joint. External surface of chela set with short, coarse, dark setae; cornute, conical tubercles on upper margin, rounder inferiorly; lower margin smooth and dark coloration expands on to palm. Pereiopods with coarse dark setae, merus, carpus prominently spinose on superior margin.

Remarks

Balss (1938) wrongly synonymized *P. pubescens* Dana, 1852 and *Chlorodopsis melanodactylus* A. Milne Edwards, 1873 with *P. pilumnoides*. In the same paragraph he also synonymized *Chlorodopsis palaoensis* Sakai, 1936. Since the description of Sakai is based on two females, this synonymy of Balss is difficult to confirm because the black coloration on the cheliped of females is not diagnostic (see discussion). Further, the types of *Ch. palaoensis* could not be located. The specimen of *P. pilumnoides* identified by Gordon lacked (originally) chelipeds, making certain determination difficult. Material assigned to *P. pilumnoides* by Balss (1938b), Tweedie (1950a) and Guinot (1958) all belongs to *P. concors* sp. n. A specimen of *Ch. pilumnoides* identified by Serène and Luom was later redescribed by Serène (1971) as *P. maotieni*. All specimens identified by Garth (1964) were reidentified as *Pilodius scabriculus* and the *P. pilumnoides* of Takeda (1989) cannot be confirmed.

Distribution

From Singapore to the Ryukyu Islands, Japan and Fiji (Fig. 26). Records from the Indian Ocean are dubious; specimens of *P. pilumnoides* identified by Barnard (1955) were redetermined as *P. spinipes* and *P. paumotensis*, and those of Laurie (1906) pertain to *P. flavus*. The Andaman Islands and Mergui Archipelago material of Alcock (1898) were not made available for study.

Type status

Type series extant, see material examined The Natural History Museum, London. Type locality Singapore and Philippines.

Description

Regions of carapace nearly indistinct, surface granulate, evenly covered with short fine setae. 2M entire. 1P uniformly granulate; sinuous transverse row of adjoining peariform granules posteriorly on 2P. Submedian frontal lobes arched, denticulate, separated by 'U'-shaped emargination; lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth well defined, curved, terminating in chitinized spine. Anterior margin of cheliped merus spinose. External surface of cheliped carpus tuberculate, with furrow parallel with palmar joint. External surface of chela with well-spaced, large rounded tubercles on upper margin, diminishing in size inferiorly. Pereiopods setose, merus, carpus distinctly spinose on superior margin.

Remarks

Chlorodopsis melanodactylus was described and figured by A. Milne Edwards (1873) from New Caledonia, and it was this name that became widely used in the literature. Miers (1884: 531) identified *Chlorodopsis melanodactylus* from Africa or Eagle Island (now *P. spinipes*), Seychelles (now *P. spinipes*), Etoile Island (now *P. flavus*) and Oriental Seas (now *P. pubescens*). The *Chlorodopsis melanodactyla* of Lenz (1905) from Zanzibar pertains to *P. spinipes*. Balss (1938a: 59) synonymized both *P. pubescens* Dana and *?Chlorodopsis melanodactylus* A. Milne Edwards with *C. pilumnoides* (White, 1848), a decision not supported by Tweedie (1950: 12) who claimed (as did Miers, 1884: 531) that the pigmentation found on the male cheliped of *P. pubescens* extended only very slightly on to the palm (propodus), a character that separated the species from *P. pilumnoides*. Although this character is adequate for separating these two species, part of Miers' material and Tweedie's (Serène, 1984: 244) was not *Pilodius pubescens*. A male syntype of *C. melanodactylus* was examined by Serène and Luom (1959: 316), and they concluded that the species of A. Milne Edwards agreed perfectly with the description and plates of *P. pubescens* Dana, 1852. S. Bock collected a single male from Namuba, Viti Levu, Fiji, which was identified by Balss (1938a: 60) as *C. pilumnoides* and subsequently formed part of an exchange by the Munich Museum with the NHM. This male was redetermined as *P. pubescens*. Balss (1938a: 57) also synonymized the *?Pilodius pubescens* of Nobili 1907: 395 with *Pilodius flavus*.

Distribution

From Nha Trang Bay, Vietnam to Samoa (Fig. 27). Not recorded from the Indian Ocean. Specimens recorded as *Pilodius pubescens* from Seychelles (Serène, 1977) and *P. spinipes* and the record of Tweedie (1950b) from the Cocos Keeling Is. must be considered dubious.

Type status

The type material was destroyed at the time of the Chicago fire, because Stimpson had on loan from the Smithsonian Institution a large collection of Crustacea including many type specimens of James D. Dana. Sooloo (Sulu) Sea, or Balabac Passage, were quoted by Dana as the type locality.

Description

Regions of carapace well defined by broad smooth deep-cut grooves, 1L–4L conical shaped, 2M entire, dorsal surface shagreened, with few scattered setae. 1P uniformly granulate; sinuous transverse row of adjoining pearliform granules posteriorly on 2P. Submedian frontal lobes trapezoid, crenulate, separated by distinct ‘U’-shaped groove, lateral lobes acuminate tubercles. Anterolateral margin tridentate, three equally prominent, large hook-shaped teeth lacking ancillary spines or granules. Anterior margin of cheliped merus prominently spinose. External surface of cheliped carpus and propodus studded with large, conic tubercles, smaller and obsolescent ventrally on propodus. Pereiopods fringed with long setae, superior margin of carpus, merus, propodus prominently spinose.

Remarks

The confusion between *Pilodius pugil* and *P. spinipes* was first noted by Nobili (1906, 1907). He stated that the description of *Chlorodopsis spinipes* given by Alcock (1898) was similar to the figure of *P. pugil* by Dana (1855: pl. 12, fig. 8a). Ramadan (1936) erroneously synonymized the *Chlorodopsis spinipes* of Nobili (1906), Laurie (1915) and Balss (1924) and the *Chlorodopsis woodmasoni* of Alcock (1898) with *Ch. pugil*. All this material belongs to *P. spinipes*. Serène and Luom (1959: 320) assigned the *Pilumnus globosus* of Boone (1934) to *P. pugil*.

Distribution

Balss (1938a: 62) remarked that only *P. spinipes* occurred in the Red Sea, and he considered *P. pugil* to be an oriental species. However, Guinot (1964: 68) identified three small *Pilodius* specimens collected in the Red Sea as *P. pugil* and showed that while *P. spinipes* was indeed restricted to the Indian Ocean, *P. pugil* had a wider distribution which extended from the Red Sea to the Tuamotu Archipelago (Fig. 28).

Type status

Dana's type specimen is no longer extant; it was destroyed in the great fire of Chicago while on loan to Stimpson. Type locality Upolu, Samoa, Pacific and Balabac Passage, north of Borneo.

Pilodius scabriculus Dana, 1852

(Figs 14A–G, 37B, 43D)

Pilodius scabriculus Dana, 1852: 80, 1853: 220, 1855, pl. 12, fig. 9; Nobili, 1907: 394; Forest and Guinot, 1961: 91, fig. 83a, b, fig. 84, 86; Guinot, 1967: 268; Serène, 1968: 80 (list); Peyrot-Clausade, 1977a: 27, 1977b: 213 (list); Thomassin, 1978: 64 (Appendix 3); Serène, 1984: 244; Dai *et al.*, 1986: 309, pl. 44(2), fig. 166(5); Dai and Yang, 1991: 332, pl. 44(2), fig. 166(5).

Chlorodopsis melanodactylus: Tweedie, 1950b: 121, pl. XVII d, e.

Chlorodopsis spinipes: Sankarankutty, 1962: 139, fig. 40, 41. **non** Heller, 1861.

Chlorodopsis venusta Rathbun, 1907: 49, pl. 1, fig. 5, 1911: 226; Calman, 1909: 705 (list); Ward, 1941: 11; Tweedie, 1947: 27 (list); Serène and Luom, 1958: 131, pl. II, fig. C, pl. III fig. e, pl. IV, fig. f.

Chlorodopsis venusta: Balss, 1938a: 53 (part).

Pilodius etisoides Takeda and Miyake, 1968b: 186, fig. 2, pl. 8 C, D.

Chlorodopsis pilumnoides: Garth, 1964: 140 (list). **non** White, 1848.

non *Chlorodiella venusta*: Balss, 1938a: 53 (part) = *Liocarpilodes integerrimus* (Dana, 1852).

non *Chlorodopsis scabricula*: Rathbun, 1906: 859, 1907: 50, pl. 1, fig. 3, pl. 9, fig. 5 = *Phymodius nitidus* (Dana, 1852).

Description

Regions of carapace nearly indistinct, better defined laterally, dorsal surface shagreened, sparsely setose. 2M entire. 1P uniformly granulate; sinuous transverse row of adjoining pearliform granules posteriorly on 2P. Submedian frontal lobes rounded, minutely denticulate, separated by shallow notch; lateral lobes triangular, denticulate. Anterolateral margin quadridentate, teeth granulate, anteriormost smallest, lacking curved apical spine. Anterior margin of cheliped merus distinctly spinose. External surface of cheliped carpus tuberculate, with furrow parallel with palmar joint. External surface of chela with conical tubercles on upper margin, smaller and obsolescent inferiorly, lower margin shagreened. Pereiopods sparsely setose, merus, carpus with conical tubercles on superior margin.

No data; 1♂ 8 mm, 2 juv.; formerly *Pilodius pilumnoides* det. J. S. Garth (USNM no reg.).

Remarks

Material identified by Rathbun from Honolulu (1906) and Tahiti (1907) as *Chlorodopsis scabricula* was assigned to *Phymodius nitidus* by Forest and Guinot (1961). Balss (1938) synonymized *Chlorodiella asper* Edmondson, 1925 with *Chlorodiella venusta*; however, Serène 1984: 263 assigned this material of Edmondson to *Liocarpilodes integerrimus* (Dana, 1852). Forest and Guinot (1971) considered *Chlorodopsis venusta* and *Chlorodiella venusta* as junior synonyms of *Pilodius scabriculus*. Specimens identified by Garth (1964) as *P. pilumnoides* belong to *P. scabriculus*. The *Chlorodopsis spinipes* of Sankarankutty (1962) and the *Pilodius etisoides* of Takeda and Miyake (1968) were assigned by Serène (1984: 245) to *Pilodius scabriculus*.

Distribution

Recorded from the Island of Europa, west of Madagascar, to Polynesia (Fig. 29). Not recorded from mainland east Africa, Red Sea or India.

Type status

Type specimen destroyed in the great fire of Chicago while on loan to Stimpson. Type locality Balabac Passage, South China Sea.

Description

Regions of carapace well defined, deep cervical groove in mesogastric region, surface unevenly granular, sparsely setose. 2M partly divided into two longitudinally. 1P uniformly granulate; sinuous transverse row of adjoining pearliform granules posteriorly on 2P. Submedian frontal lobes rounded, denticulate, separated by 'U'-shaped notch, external lobes small, spine-like. Anterolateral margin quadridentate, teeth well defined, clearly separated, curved, furnished with ancillary spines distally, this being most pronounced in 2nd tooth. Anterior margin of cheliped merus spinose. External surface of cheliped carpus with large, conic tubercles, furrow parallel with palmar joint. External surface of chela closely set with long conical tubercles, smaller inferiorly, lower margin granulate. Pereiopods sparsely setose, superior margin of carpus, merus, propodus spinose.

Remarks

Nobili (1906: 270, 1907: 395) commented on the confusion that had existed over the descriptions of three species *Pilodius pugil* Dana, 1852, *P. spinipes* Heller, 1861 and *Chlorodopsis woodmasoni* Alcock, 1898. The *Ch. spinipes* description by Alcock agreed with Dana's figure (1855: pl. 12, fig. 8a) of *Pilodius pugil* and fitted perfectly with Nobili's examples. After examining numerous specimens of *P. spinipes* from the Red Sea, the type locality of Heller's species, Nobili concluded that they accorded well with *Ch. woodmasoni* of Alcock, but Nobili was unable to confirm this statement as Heller's types were no longer extant in the Vienna Museum. However, Serène (1984: 243), after examining Alcock's syntypes of *Ch. woodmasoni*, supported Nobili by saying that this species was identical to *P. spinipes*. The extreme variation found in *P. spinipes* (pl. 2A, B) was shown by Serène (pls XXXIVa, b), from specimens collected in Djibouti (MP B.8057). Further, the material assigned by Serène (1984: 243) to *Pilodius* aff. *spinipes* (pl. 9A) was examined and it was found to be within the morphological variation exhibited by *P. spinipes* Heller. Serène suggested that *Chlorodopsis melanodactyla* (now as *Pilodius spinipes*) of Miers (1884: 531) from Seychelles, Barnard's (1955: 3) *Pilodius pilumnoides* (ovigerous ♀ now *P. spinipes*) from Delagoa Bay (Baia de Lourenco Marques) Moçambique and McNeill's *P. spinipes* from Queensland (1968: 74), Australia (now *P. nigrocrinitus*) should be re-examined. Michel's *Chlorodopsis spinipes* and *C. woodmasoni* from Mauritius (1964: 24) were redetermined as *Pilodius pugil* Dana, 1852 and *Phymodius drachi* Guinot, 1964 respectively.

Distribution

Pilodius spinipes is restricted to the Red Sea and Indian Ocean (Fig. 30). The redetermination of McNeill's material leaves Alcock's Mergui Archipelago recording (*Chlorodopsis woodmasoni*) (1898: 171) as eastern-most Indian Ocean record.

Type status

A recent inquiry (Pitkin, personal communication) confirms that the type specimen is not extant in the Vienna Museum. Type Locality: Red Sea.

Discussion

Previous revisors of *Pilodius* Dana, 1851 were unsuccessful in resolving the complex taxonomic problems associated with this taxon. Many factors have contributed to the situation where 43 species (Table 2) have been described and referred to *Pilodius*. A major part of the problem is that only male specimens can be positively identified to species. Male pleopod morphology had great value as an effective differentiating character between the many old and new species established and male cheliped coloration pattern provide further stable identification features. Other characters are more variable; for example the difference in cheliped morphology between mature and immature specimens of the same species is marked, (Figs 40D, 41A, 42B, C), also variation of exoskeleton spinature in males can be extreme (Figs 38A, B, 39A).

Females of *Pilodius* are almost impossible to identify to species because their cheliped coloration patterns are different from those of the male counterpart (Figs 40A♂, 44A♂, 44B♀, 44C♀), but are almost uniform between species (Figs 44B♀, 44C♀). Takeda and Miyake (1968b) based their description of *P. etisoides* on a single ovigerous female and, although this specimen was examined during the present study, the validity of the species cannot be confirmed in the absence of a male. Rathbun based

the description of *Pilodius flavus* on an immature female holotype measuring 9 mm in carapace width. She later described the same species under a different name, *Chlorodopsis melanospinis*, from a mature male specimen (Fig. 40D) and a number of paratypes. Examination of available *P. flavus* and *Ch. melanospinis* material enabled the present authors to synonymize the two species. This decision, although correct under the rules of nomenclature, makes the type worthless as a morphological representative of the species *P. flavus*. The ovigerous cotype of *Ch. kauaiensis* described by Edmondson from Kauai, Waimea, Hawaii (Bernice P. Bishop Museum reg. S 6876), was examined and the prolongation of the basal antennal segment was absent. Consequently, the antennal flagellum was not excluded from the orbital hiatus and therefore this species has been assigned to *Pilodius* erroneously.

In Table 2, 14 species are junior synonyms. The creation of some of these could have been avoided if the available type material of other species had been examined first. For example, *Chlorodopsis (Cyclodius) palaoensis* Sakai 1938 is *Pilodius pilumoides* (White, 1847), the types of which are extant and available for study. Unavailability of material may have caused many problems; the type specimens *P. pubescens*, *P. pugil* and *P. scabriculus*, *P. granulatus* and *P. nigrocrinitus*, were destroyed in the great fire in Chicago, 1871. This caused confusion between the identifications of *P. spinipes* and *P. pugil* and precluded the precise identity of *P. granulatus*. Two brachyuran collections are not available for study, the material of Sakai and Alcock, both are extant. The examination of *Ch. melanochira*, *Ch. pilumoides*, *Ch. spinipes* and ?*Ch. nigrocrinata* as determined by Alcock (1898) would have solved many distribution and taxonomic problems, however the Zoological Survey of India did not make this valuable material available to the authors of this current study.

Key to species of *Pilodius*

1a	2M entire	2
1b	2M partly divided into 2 longitudinally	5
1c	2M divided into 2 longitudinally	6
2a(1a)	Anterolateral margin of carapace 3-dentate	<i>P. pugil</i>
2b(1a)	Anterolateral margin of carapace 4-dentate	3
3a(2b)	2P with two parallel transverse rows of adjoining pearliform granules, anterior row medially disjunct.	<i>P. paumotensis</i>
3b(2b)	2P with single sinuous transverse row of adjoining pearliform granules	4
4a(3b)	Carapace densely covered with short setae	<i>P. pubescens</i>
4b(3b)	Carapace sparsely covered with setae	<i>P. scabriculus</i>
5a(1b)	Carapace and pereiopods profusely furnished with dark bristly setae; upper margin of pereiopodal merus, carpus and propodus set with conical tubercles	<i>P. nigrocrinitus</i>
5b(1b)	Carapace and pereiopods covered with long, light-coloured setae; upper margin of pereiopodal merus, carpus and propodus set with long slender spines	<i>P. flavus</i>
6a(1c)	3M tripartite.	7
6b(1c)	3M entire	8
7a(6a)	Anterior lobe of 3M not reaching anterior margin of 2M	<i>P. areolatus</i>
7b(6a)	Anterior lobe of 3M surpassing anterior margin of 2M	<i>P. miersi</i>
8a(6b)	1L-5L with cornute conical tubercles	9
8b(6b)	1L-5L lacking cornute conical tubercles.	12
9a(8a)	Lower external surface of cheliped smooth	<i>P. concors</i> sp. n. (Fig. 40C)

9b(8b)	Lower external surface of cheliped granulate	10
		(Figs 40B, 41C, 42D)
10a(9b)	Anterior margin of cheliped merus spinose	11
10b(9b)	Anterior margin of cheliped merus granulate	<i>P. maotieni</i>
11a(9b)	Dark coloration restricted to fixed finger only of chela.	<i>P. cephalalgicus</i> sp. n. (Fig. 40B)
11b(9b)	Dark coloration extends on to manus of chela	<i>P. pilumnoides</i> (Fig. 42D)
12a(8b)	Cheliped carpus with two furrows anteriorly	<i>P. moranti</i> sp. n.
12b(8b)	Cheliped carpus with a single furrow anteriorly	13
13a(12b)	2P with two parallel transverse rows of adjoining pearliform granules, anterior row medially disjunct.	<i>P. granulatus</i>
13b(12b)	2P with single sinuous transverse row of adjoining pearliform granules	<i>P. spinipes</i>

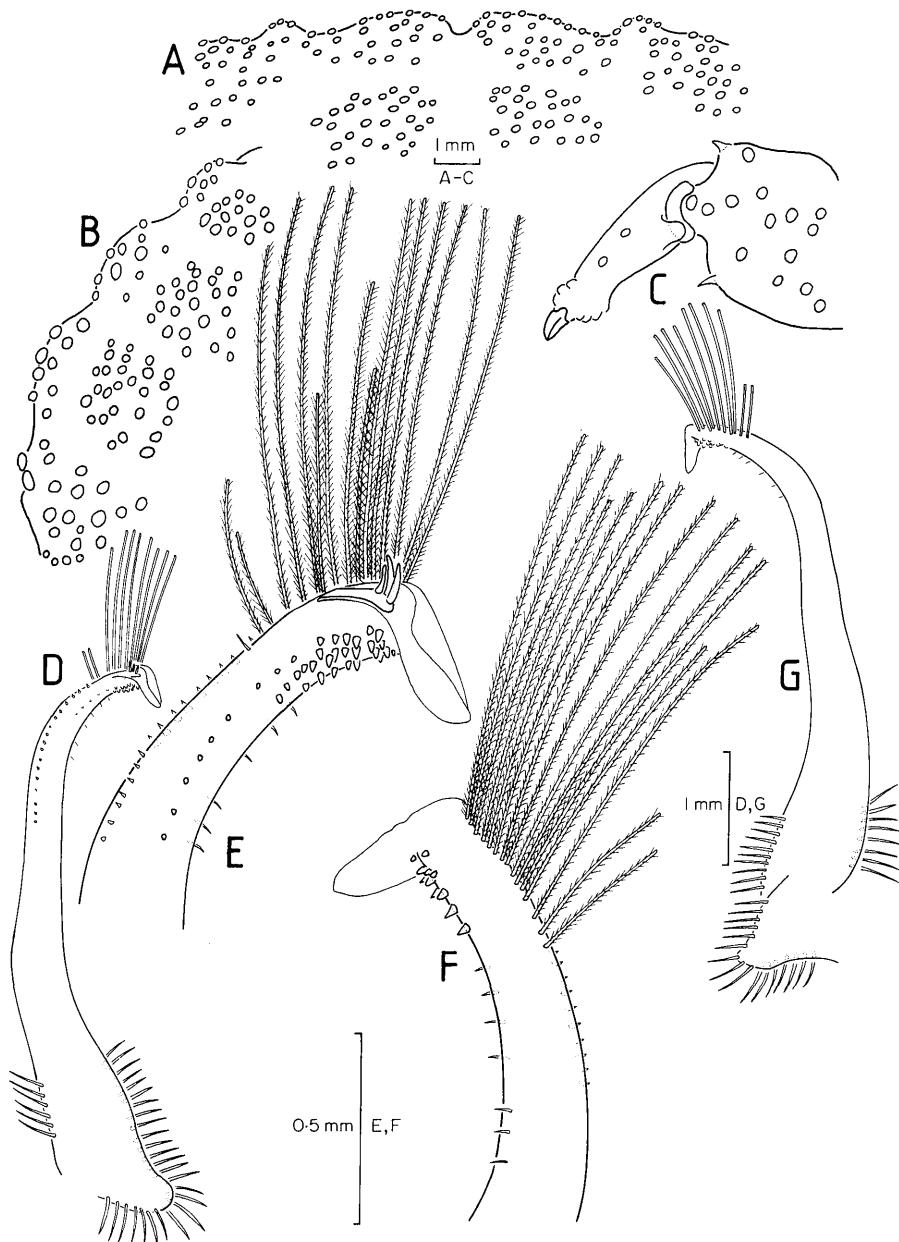

FIG. 1. *Pilodius areolatus* (H. Milne Edwards, 1834); NHM reg. 1931.7.24.95–100; (A) frontal margin, (B) left anterolateral margin, (C) propodus and dactylus of left 5th pereiopod, (D, E) ventral view of left pleopod, (F, G) dorsal view of left pleopod.

Acknowledgements

We thank our colleagues who entrusted us with material, without their help and support this paper would never have been completed: Harold Feinberg (AMNH); Roger Springthorpe (AM); K. Wouters (IRSNB); Beatrice Burch (BBM); Teru Aki Uchida (ZLKU); Claude Michel (MI); Alain Crosnier (ORSTOM, c/o MNHN); Peter Ng (NUS); Vu Do Quynh (OINT); Peter Davie (QM); Michael Türkay (SMF); Michelle van der Merwe (SAM); Ray Manning (USNM); Ray Symonds (UMZC); Peter Hogarth (UY); Katsushi Sakai (SWU); Linda Pitkin (NHM), while on study leave to Vienna Museum combed the reference collection for the type of *Pilodius spinipes* Heller, we thank her for this effort. We are grateful to Phil Hurst, NHM Photo Unit, for the photographs reproduced in this paper.
