OCCURRENCE OF TWO LITHODID CRABS
(CRUSTACEA: DECAPODA: LITHODIDAE)
IN THE COLD SEEP ZONE OF THE SOUTH
BARBADOS ACCRETIONARY PRISM

Enrique Macpherson

Abstract.—Two species of lithodid crabs from a cold seep area south of the island of Barbados, Caribbean Sea, are reported. One of the species, Paralomis arethusa, is new, and is described. The other species is Lithodes manningi Macpherson. This is the first report of representatives of this family in areas of emissions of chemically reduced fluids.

The discovery of new communities associated with emissions of chemically reduced fluids has received great attention in the last years (e.g., Jones 1985). These benthic assemblages were first discovered at hydrothermal vents in the Galapagos Ridge (Lonsdale 1977), and more recently "cold-seep communities" have been found in the Caribbean area (Jolliver et al. 1990), Oregon (Kulm et al. 1986) and Japan (Laubier et al. 1986), revealing the existence of organisms closely related to those inhabiting hydrothermal vents. The study of the fauna of these zones has revealed the existence of many new forms exhibiting adaptations of great scientific interest (e.g., Hecker 1985).

The decapod crustacean fauna of these ecosystems has been studied by several authors (e.g., Williams 1980, Williams & Chace 1982, Williams & van Dover 1983, Williams & Rona 1986, Guinot 1988, Saint-Laurent 1988, Guinot 1989). The discovery of two species of lithodid crabs, one of them new, in the cold seep community south of Barbados is the first report of this family in these zones.

The specimens are deposited in the Musée national d'Histoire naturelle, Paris. Measurements given refer to the length of the carapace, excluding rostrum (CL), and the maximum width of the carapace, excluding the lateral spines (CW).

Paralomis arethusa, new species
Figs. 1, 2

Material examined.—Holotype. DIAPISUB Expedition, sta DS01/2, 10°19'64"N, 58°53'42"W, 1691 m, 24 Dec 1992, Female (CL 15 mm, CW 14.5 mm).

Description.—Carapace as long as wide, somewhat hexagonal in contour. Dorsal surface of carapace covered with minute granules of various sizes, but without spines. Regions well-defined. Gastric region more prominent than others, with thick granule on apex and 2 thick granules posteriorly, near the gastro-cardiac groove. Cardiac region more prominent than branchial regions. Each branchial region with 1 thick median granule.

Rostrum with straight lower median spine slightly directed downwards, smooth ventrally; with 2 slightly divergent dorsolateral spines.

Carapace margins armed with few spines. Postocular spine not overreaching cornea. First anterolateral spine larger than postocular. Three or 4 spines of various sizes and several large granules on each branchial edge. Posterior margin smooth.

Abdominal segments covered with minute granules.

Ocular peduncles with distodorsal spine. First segment of antennal peduncle with 1
Fig. 1. *Paralomis arethusa*, new species, holotype, female, CL 15 mm. A, dorsal view; B, anterior part of the carapace, lateral view; C, abdomen; D, right cheliped; E, third left ambulatory leg.
spine on outer margin. Second segment with 2 spines on outer border. Acicle with large central spine not overreaching antennal peduncle, and 2 spines on outer border; inner border smooth.

Chelipeds subequal in length, right stouter than left. Merus bearing 2-3 spines and few granules at end of dorsal border, 2 small spines on outer surface. Carpus with 3 strong spines on dorsal border, rest of article smooth, except for some granules. Dorsal border of hand with 5-6 small spines, few granules on outer and ventral surfaces. Fingers without granules, bearing numerous tufts of setae.

Walking legs moderately long and depressed. First and second walking legs slightly longer than third.

Third leg 1.5 times carapace length. Coxa with several granules. Merus 3 times longer than high, about twice carpus length, and slightly longer than propodus. Row of 8-9 spines on dorsal border, another row of 9-10 spines on ventral margin and 4 spines on proximal half of posterior surface. Carpus with row of 7-9 spines on dorsal margin. Propodus 2.5 times longer than high, somewhat longer than dactylus, with row of 10-11 spines on dorsal margin and another row of 10 spines on ventral margin. Dactylus slightly curved, with row of 13 cornaceous spines on ventral margin; tuft of setae along dorsal border.

Etymology. —The name refers to the Nymph of the Fountains, Arethusa, of the Greek mythology, in reference to the emissions of fluids that characterize these areas.

Remarks. —There are about 47 species in the genus Paralomis White, 1856 (Macpherson 1988, 1992), four of which occur in the Caribbean area: P. cubensis Chace, 1939, P. grossmani Macpherson, 1988, P. pectinata Macpherson, 1988 and P. serrata Macpherson, 1988. The new species resembles P. formosa in the shape of the carapace and the armature of the chelipeds and legs. However, the two species can be readily separated by several characters. P. formosa has several well-developed spines on the dorsal surface of the carapace, whereas these spines are absent in the new species. The antennal acicle bears two or three spines on each side in P. formosa, whereas only two on the outer border in P. arethusa.

Lithodes manningi Macpherson, 1988

Material examined.—DIAPISUB Expedition, sta DS16/7, 11°13'82"N, 59°21'82"W, 1236 m, 8 Jan 1993, Male (CL 15.6 mm, CW 14.0 mm).
Remarks.—This species was described from two large specimens (CL 103 and 120 mm) collected in Dominica and French Guiana, at depths between 640 and 777 m. Except for the size difference, the specimen examined agrees quite well with the type specimens.

Acknowledgments

I am very grateful to Karine Olu (IFREMER, Brest, France) for providing the specimens used in this study. The photographs were taken by J. Biosca.
