A. marroskeles Alcock el Inderson, A. mahabaricus deptopus De Van, A. nonaller Nemsley, A. paradentipes Combiore, A. proseuchirus De Man, X. pustulosus Bamer el Bamer al X. patulilus Bamer al Bamer.

[^0]The MUSORSTOM Expedition earrien un dredgings in the waters off the Lubang lisands. southwest of the entrance to Manila Bay, and a single dredging of the entrance Lo Manila Bay. The dredgines produred 19 species of alpheid shrimp of the genera Vennalpheus gen. nov.. Symalpheas and Apheas, all of which are new recorts for the Philippine Archipelago and include three species new to science; many of the raptures represent new depth records for the individual species (1). All samples save two (which will be noled in the lext below) ame from waters over 100 m in depth and most came from about 2001 m deep: the full detail:

On each salion are wiven elsewhere in this volume. One sample rame from a commerial shrimp Irawl and was puretaned in the Manila fish markel. In the text the speries wilhin parlo genus are arranged aphabeliably. All specimens. including the type series, will the deposiled in the Musemm mational d'llistoire naturetle exerptas noted. We have added records of lwo addilional specimens, one of Xeme alpheus sibogue (hir Man), and ome of $1 / 1 /$ heus rompressus spe nov. from the collections of the I nimoritetets Zoologiske Museum, Copentagen, Denmark after this paper was acoepted for publicalion.

## SYSTEMATIC ACCOUNT

## Nennalpheus gen. nor.

## DIAGNOSIS

General body form as usual for members of the family. Rostrum lriangular. areute and short. dorsally rounded and wilhout carina. Wilhoul orbilal houds. will or without llattened orbital (or supracormeal) leeth. Plerygostomial marein rounded and not protruding. Eyes well developed, visible at leasl in part in laleral view, concealed or parlially conrealed? in dorsal view. Orbitoroslral promes larling.

Antenmular peduncle relatively larese styonerile with lateral loolh well developed; ouler lagellum wilh base of several distincl arlicles, a stiferoun lobe and the usmal thavellar porliong. Araphorerite nortatal with looth and squamous portion well developed: barpocerite long: hasicerile with interolateral projecting toolh 1 ).

Mondhparts similar lo those foumd in Mphas.
First pair ol rhelipeds symmelriath, will ehelate entarged and rarried extended; rhela proper rarried in inverped position. Wilh daclylus lyine on sagifal phane ol body but inlerior 10 palm and pollex. Both lingers bearing rounded and exactly fithog teeth in proximal half; daclylus wilh shohl bul hardromed rounded ridge or rerest distal lo teelh filling into shatlow but well-defined groove on pollex: dishally lingers arutely hooked and erossing. Palm subrylindrical in section. Proximoinferior margin ol palm produced into small "heel" or knob lo make rarpopropodal artirulation. Carpus mot ryathiform hut in lateral view of a rounded sub-rectanmular shape lying at angle to merus, with carpo-propodal articulation in inferior third of distal matern, merorarpat artirulation in superior half of proximal marein: with distal margins extended into acule or roumbed llal teeth. Merus Irianoular in section, somewhal twisted: ishiomeral articulation apparently not fully
fused. Note: It may be possible that the rhelipeds undergo marked rhanges with erowlh, similar to some species of thanas: see diseussion under $A$. inarticulalus. below.

Carpus of second legs of tive articles with the lirst arlirle longer lhan sum of remaining four.
'Third leg stender, wilh isrhium bearing several s somos sines; merus and carpus slender and unarmed; propodus bearias setae lo slender spines; dactylus long, somewhal curved, simple.
serond pleopods of males bearing appendir masculina as in Mphpas: ol herwise pleopods of males and lemales of similar size and derelopmeat. Pleura of abdominal segments of similar size and developmenl in both sexes, with dirst four rounded, fifth with posierior mareinslightly projected and subacule. Dosterior margin of sixh abrominal segment lateroventrally either projecting into a triangular articulated pleuron or lappel or a small truncate process.

Thelson slemder, wilh dorsal amd postero-lateral spines well developed: fip convex bul nol ereafly produced; larking in anal lubereles. (ropods nommal.

Bramohial formulat as in . Mphous: E) pleurohranchs, 1 arthmoheanch, s enipodiles with mastigobranchs on hases from thim masilliped lo fourd pereiopod. setohranolis from dirst lo fifth pereiopoots.

## Type species

Hpheopsis vilugae [)e Man (1910: :307: 1911: 181,

It was our original intent lo use N. inarliculatus, described below, as the type speries for this genus. hat when we included ibs MAN's species in this semus wr derided it would be better lo use a species wilhan intad holotype as represent al ive of the genns. Furbler reinforeing thal derision was the later diseovery ol a serond specimen ol N. sibogae in the collection of I Enversitetets Zonloriske Museum, Coprobbagen, bemmark. We were able to examine Ine Ha*'sole sperimen, a 16 mm male, through the

[^3] of his hololype showed that there is an acule ampular projection similat lo. X. inarliculatas see fig. Ia.
rourtesy of Dr. Sjouk Pinkiter of the Zoologiach Museum, Smsterdim; it was onllected at 70 m in Gapeh strat, Indomexia. The Danish sperimen is a 15) mm female (warying what appears to be two immature eqgs) from Lombok Slrails, slightly over 500 km west of the type tocation dalathea station
 the female specimen is in good condition with symmetrical first chelipeds carried extended: the dilterences between it and the hololype are slight and only in the
 as long as broad, and the meri of the third legs are 12.2 rather than 10.6 times an long as broad. These dillerences in proportion may he spxal, or may be merely within the range of normal variation.

## Discussion

In most characteristios this genus shows elose relationship to the genus Mpheopsis Coutiere. The two genera are similar in body form, in branchial formula, in the development of the anterior portion of the carapace and the coverage of the eyes (the eyes are more exposed in N. inarticulalus but that is probably due to injuries sulfered in the (rawl), and in all appendages save the firso eheliped. White the Chelae are different in morphology, in both genera they are carried extended, nol lodded back umder the rephalothorax.

It is the form of the chelipeds that separales this genus from all others, particularly in combination with other chamateristics. The amost rectangular form of the carpus is unique wilhin the family. In the form of the chela. this qenus is closest to $t$ mphibetaens Coutiere which alsu bears a low rounded ridge in the distal portion of the daclylus that fits into a corresponding cavily on the pollex, and carries adhesive plaques on the opposing palmar and digital surfaces. In 1 mphibelarus the more proximal portion of the dadylus bears only one rounded tooth instead of serrate teeth: more important. however. is thal the chelae are carried folded back under the body and show extreme asymmetry see Codtiene, Is 9 s. figs. 217-218). Imphibelaens alan larks a distind rostrum, similar to Befaers.
some speries in three wenera carry their chelare in an inverted position with the propodal finger uppermost. at least when extended, as does Vemalphens. Three species in Ahanas. A. borradailei (Couliere). A. remucosus Banner and A. polynesica Banner \& Banner. would have the dactylus in a somewhat inverted position were the chelat extended: in these the fingers lark the low ridge and corresponding cavily. the patms are expanded and flat fened. and the carpus is elongate and expanded to acommodate the flexure of the appendage: in inddition, of course. the speries have the ol her charamberisties of

The gemus. surh is exposed rameas. Arefopsis amabilis the Man also carries the lingers on both chelae in an imserted position, but they are withoul the ridge and groose and are asymmetrical in development (B. \& B. Aust. Ill): this genus is characterized by the ventral keel on the rostrum. Amosl all members of the genus Bolapus Stimpson cary their lingers inverted, with chelae rarried extended and of slight asymmetry, hut they lark the ridge and groove of Nemalphens; probably more important, none of these species have a distinet rosisum.

Another puint of comparison might be the adhesive plaques which serve to hold the dactylus in the open position. Amphibelaens has already been contrasted; the obher genera are $1 /$ hheus leabricius. Melalphete: Coutiere, Racilius Paulson and posibly Pomognathus Chare (for the las demus the presence or absente of the plaques was not mentioned in the description\}. All four ol these genera usablly have the well-ileveloped plunger and sorkel on the hasal portions of the fingers and all sase Racilias have well-developed orbital hoods. In Racilus the swollen whital hoods are latking but the single speries in the eronus is characherized by extreme laleral compresion.

The lwo species plared in . Menmalphens have large -helipeds that are almost identical (for a possible small cheliped, see under $N$. inarticulatus, below). The only difference belween the two species lies in the ridge or erest on the diaflylus and the rorresponding eroove on the propodal tinger which are slightly beller doveloped in N. sibugar than in N. inariaculalas. X. sibogue, however, hears strong and definite enrneal teeth, no trace ol which are found in.$\lambda$. inarticulalus. Most important. however, are the: presence of articulated pleura in. . sibogap, wilh both known sperimens showing a line of arliculation between the Iriangular lappet and the exaskeleton of the Gith abdoninal somite (fige. I s); in X. arliculdus, on the other hand. the posterolateral margin of the fith abdominal somite protrudes in all four specimens as a thatlened lobe with two low and slight cusps on its margin and without a trace of an articulation (fig. $1 \underline{g}$ ). We realize that the presence or absence of articulated pleura is usually considered as a chamateristir constant within a genus; Yanow has separated Beteopsis from Betaens solely upon this characteristir. However, we believe that the presence of almost identical chelipeds on the I wo species far outweights the presence or absence of articulations on these pleura To us it is far easier to conceive of the evolutionary lose of a slight thexibility in these lappets as accorded by the feeble articulation than it is for the parallel bul separate poolution of the unigur chela and its men more strange carpus.

This new genus permils further speculation on
the evolution of the phuger and socket of the laree - Thela as is found in the five "higher gemera" of the family: Apheas, Melalphens, Marilius, Symalphous Bate and Prmagnathus Chace. In the "lower genera" - other than Amphibetaens and Venmalphens the tingers are either without armalure or have relatively simple teeth. The low rounded ridge of the dactylus and corresponding groove of the pollex found here and in Amphibetaens. both located distal lo the middle of the lingers, with the more primilive proximal leeth found in . Venmalpheus, are unlike the armature found in other lower genera. The adhesive plagues found in these lwo lower genera and all of the higher genera save signalphous and possibly Pomagnathus) permit the heasy museles of the palm Lo strain before the plapues release. permetting the violent dosure of the fingers. It would take lithe exolution lo mowe this crest and groove proximally. in the process losing the proximal serrale teelh, lo a low rest and elongate groove surh as found in Aphens chiragricus Milne-Edwards or 1. dislinguendus De Man. This, Hen, could easily evolse into the semi-cylindrical plunger and deep sockel as found in many other speries such as . 1. pacificus Dama. Cortomes, in his monograph (1899: : 3001 has placed the genus I/pheopsis as representing the
 of the rese groove and adhesive plaques is another step abong the line. We are not sugresting that either . 1 mphibelacts. with its darqe chela carried in a llexed condition. or Xenmalphems, with its inverted chela and strage carpus. represent the direct evolutionary line lowards . Mphens, bul maher that they are derived from some early stem-form thal was to give rise to . $1 / p h e$ us.

Because we postulate this genus is derived from the stem-form of . Hphens. but revtainly not in the direct line we have applied the Greek word nennos. murle. as a prefix to . Wphens. the name of a Gereek river and a lireek grod.

Nennalpheus inarticulatus sp. nov. (fig. 1)

Hololype: 30 mom mate from MISORATOM at 20.

Alotype: 31 mm oxigerous female from same station as holotype.
Paralypes: 9 mon wherous female and 30 mom male from Ml: $120020,3^{\prime} \mathrm{E}, 191-2(\pi) \mathrm{m}$.

## Description

specimen loms and wilh eyer and bases ol antenmules and antennate probably displared anterior-

Iy in mefence to anterior sarapace. Rostrum acute, wilhout dorsal rarima, as long as broad at base, raching proximal and of first antennular article. Anterior margin aradually romaded, withoul teeth. Corneas and anteromedial lobes more than half exposed dorsally, with greater exposure when viewed lalerally. second antemnalar arlicle 1.2 times as long as visible parl of tirst: :. 5 times length of Hhird and 2.8 limes as long as broad: superior margin of first article projecting distally: and inferior margin bearing forward-sweeping plumose selae. Distal marqims ol all antemmar articles mimulely serrate and hesel wilh some fine setae. more selare dishally on first article than on distal two. Basal portion of outer thagellum of 6 articles. first article 2.5 times longer than second, other 5 articles nearly equal. inner hranch short, setiferous hut wholho visible articulalions. Stylocerite with acute lip lurned lightly outward and reaching to end of lirst antemular article sraphorerite with outer margin straisht, squamous portion broad, reaching to midde of third antemmular article, lateral looth sightly longer. Carpocerite slender, reaching past antemoles by length of third antenmular article, basiderile with shorl acule lateral tooth.

Moulhparts as usual lor family. Matio of antioles of third maxilliped begiming with hase 10: 3 : O . Proximal arlide thatened. ribbon-like in midsection.

Chelipeds larkinge on hololype and allotype: description based upon Lwo chelipeds found loose in jar with paralypes (see discussion below). Large chela camied extemed with dactylus in inverted posilions, as in belapos (in the description below, all dirertions are given at the chela is at a thy carried, mot as it "should be rarrid"). Chela slender and chongate. b . E times as long as hroal with fingers oerupying distal 1).4. Palm subeylindrical and of rather solt rhitin, wilh a possibie light, ill-define depression on lower portion of laleral face, rumning from near capal articulation to base of prollex (this may be an artifact from the solt chitin). Dadylus hithly compressed and carinate, proximally bearing a well-developed adhesive plaque and corresponding (o plaque on distal shoulder of palm; oppositional face bearing in proximal half itrong hut rounded leeth and : less well-developed teeth that intermesh with similar teeth on pollex: next third of dactylus *ighty swollen with opposilional margin slightly consex in profile. fitheng into slightly concare hamened portion on pollex: distal to his both fingers hearing concale cutting edges and terminating in strongly hooked tips that cross. Palm proximally projected at inferior side into almost cylindrical knob to make articulation with carpus: middle of proximal surface of patm shightly roncave. Carpus not cyalhiform. sub-quadrangular in lateral view. but wilh concase superior and ronsex inferior

 $r$, telsom and uropmeds.
 plura, a, b, c, f. g, h, i, k, p, q, r, s, seale a; d, e, j, l, m, n, o, scala b.
surfaces aboul twice as lone as broad and lyinge al - bearly a tigh amgle lo merus. Carpopropodal at icmation exdently providing for superomferior hexion, wilh distosuperior surfare of ramples somewhal - contare lo receive rounded end of palm when chela is bent upward. Distal margins of carpus extemded as sereral hat projedions: that on intero-matemal margin as rounded lobe that on midnuperior surfare as heod bul acule toollo, and those on medial side as rounded foult abose and rounded shoulder berlow. Ischomerus with articulation helwem artieles with al most only slight repabilitios for llexion: aboul a gluarter as longe and a thirel as broal as chela itselt. flare times as long as hrod distally, with inferion marein liatlemed. superior margin rounded. sombwhat narowed and alighly haiated proximal to midde when viewed trom superior or inferior abere
small chela in vial simitar for that of lemate of Athomas dimerphus Orlmamm. Ration of articles of small cheliped begiming with ischimm and temin-
 as long as broald, 1.15 times as long an fingers: tip of dactylux broken; tip of poltex slighly rarved. abule Merus 7.1 times as long as hatal, all antictes bearime scallered fine selar.

Kalio of aticles of recond leg: $10: 2.0: 1.2: 1.5: 2.2$.
 long as merus and bearing :3 strong spines on infernlateral surlace. Mertas 9 limes as long as broad.
 distah margin slighly projected. Propodus 10.6 as long as merus. hearime on its inferior marquan a few hairs and a pair of thin spines distally. Wartytum
 legs similar exepl is. hium of fifth legs bearing only 2 spines and fropodus bearing usual brush of selate.

Pleura of sixth abdominal segment nol arlical ated. Telson 6 times as long as posterior matein is broad. Dorsal spines large, distal pair plared anterine to midde. Immer spine of posterolateral pair strone.
 gutar. Guter mopod wilh disial articulalion.

## Discussion

None of the four specimens in the lype serits are intact and we chose the ofre mose complete as the hololype although it lacked the wholar. The lwo Che lat deseribed abore are trom Station and were detarhed in the vial with the broken male and female specimens.

It is these loose cheliperts thal present the dificulty. Se indicated in the deseriphions and tigures - (lig. 1 d-j) the chelipeds in the vial are profoundy - dissimilar. In the lwo mush smatler specimens of A. sibogue the chelipeds are symmedrical and similan
in both arces. One would presume the same symmetry would ohlain in this preces as well; on the hasis of this pramplion. we have extablished the presence of symmelrial rhelipeds as a rerterion for the ermas. If it be so. however. then the small cheliged in the vial musl he from some other shrimp that wats lo-t in the dredge haul. and if il were from all alpheid. it might well be from some speries of the genun . Whanas. Ha the vial lor stalion én were these lwo broken ofecimens. and one sercimen each of Wpheus momensheles Sheock and Smerson and signalpheses triactulhus bes Man, neibher of Whid combl have rarried suble a small chela, and mo trace of any other specimen. In farl. in
 Io wis them were no sperimens whiab would be expected lo bear this lyper of weliped.

Thus, there is a possibility that the smath cheliped may have come from one ut the lwo sperimens of ‥ inmericulahes. It shoudd ber recalled that in thamas it is not mommmon lor bollo seves to have small and rallor primilively developed symmelrical chelipeds while voung. Horn Io develop asymmetrical chelipeds, amb finally lo develop masive symmetrical chelipeds when folly malume see D. \& B.. 1960),
 (6 and 9). Therefore it is posible, bul not likely, that this rhelipert is from these specimens and that this speries may pates themoh a seribe of markedy differenl slages in rhela development.

The separation between this speries and . . . sibegue in discussed under the gemus. The name refers to the bark of an artioulation at the base of the posterolateral extensions of the mareme of the sixth abdominal serment.

The Iype ardire will be depmiled in the collections of the Muséum Xalional dollistoine Xaburelle, Paris.

Dactylus matulate. slishtly excavale on inferior surfare, 0. 3 as long as propoclus.

Trason 1 bimes as fong as broad distally: lateral mareme anderiorly comex, poibriorly comeave: posterior matroin ramded and projectine. Inner apine of pestero-laleral pair almos ? limes as longe as ouler and readhing well beyond convexily of tip. Antrerior pair of dorsal pimes pared anterior to
middle. Transverse articulation ol ouler uropod bearing a large llap as well as a small scallop.

## Discussion

The Mlisomisom paralype from it. 30 carries an intact fourth leg and a third leg lacking the propodus and daclylus. As the merus of the unathached leg of the hololype has the same lengthbreadth ratio as the third and is heavier than the fourth leg of the paratype (x.5) times as long as broad rather than 9.0 we hase presumed the loose leg of the holotype $f 0$ be the fhird. The Mtisorscolon paratype from sl. 71 has only the large "hela and one fifth leg which is lacking distal articles.

The paralype from the Caper st. Mary station is withoul chelipeds, bul it agreas wilh the MUSORSTOM specimens in the markedly rompressed body and the large llap on the outer uropod as well as the armature and proportions of the remaining appendages. However, this specimen possesses ? small orbilal teeth which are larking in the MLSORSTOM specimen. In A. collumiamus Stimpson and .1. gracilis Heller the presenee of orbital teeth is variable and without speritic or subsperitic signiticance (B. \& B.. Australia IID), so this can be a variable character in this gemus. Inasmuch as the Cape st. Mary recimen also rame from the South China sea and only ahout 1100 km distant from the MESORSTOM spermens, in a similar deph and from a similar bollom, we are lembatively ascribing the difference to mere variation, not to a regional difference at the subsperifir level.

While this speries plainly belomgs to the gemus A/phems as is shown by the coverage of the eyes. the nature of the intad appendages. the ratial fan. etce, it is unique within the gemus in its high degree of lateral compression of the body and the presence of the highty developed lobe al the distal articulation of the outer uropod. of lesser systematic: importance, bui useful for identificalion are the distal teeth on the meri of both chelipeds and the carpus of the small cheliped.

We have assigned this species to the broutostris Group allough the large chela in some rharacteristies is an extension beyond any rondition found in that eroup. In this aperies the chela, while somewhat compressed, laths the greal. compression and quadrangular erosi-section that is often lound. In a number of the species in the herirostris Group the plunger on the dactylus is low and conlluent wilh the more distal margins. and the sockel on the pollex is incomplete and open distally, hut usually the plunger is not so heary, the sorkel so diserele proximally and so open distally as this. In other characleristies, the specten is in general smilar to those of the brecirostris (iroup, as for exampla the
long lingers of the small ehelat. The spatulate condition of the walking legs and the somewhat linguiform teson. The hat eral compression of the hody and the supression of orhito-rostral grooves. here again rarried to extremes, are temdencies found in some * specter in the eroup. Diven lhe likely habilal. solt mud, is more commonly insaded by members of the brevirostris diroup than other subemeric eroups. Of course. the ortital teelh foumb in the Cape st Mary specimen are otherwise monown in the brevirostris (imous. The characteristios wiven above will separale the speries from other members of the group.

The romeats of the rexe are mot latree and law orbital hoods are preseni. bul not intlated as in an many olher members of the eroup. This lack of inthation and the high. Hhin row rum hat leand to the disappearame of the artilo-rostral erueses the seep sides of the rostrum merely curve to the thathened upper portion af the mbitals hoods which then genty curve laterally to med the adiacent areas of the caripatere.

The appeatane of the stiferous lobe on the cyentalk beyond the margins of the orbitals hoods may rellece the rondilion in life. or may be the result of damase to the sperimen from dredging for further diseussion see .1. foresti below

The deep, compresed beody probably relleets. some hishly pecialized hatitai. as does the deep body of Mifhews lollini (iuérin, and deep and highly compresed body of hacilius compressus l'autson. bolh of which are obligale commensals on living comal. An interesting parallel development in the pollex and daclylus is found between this speedes and 1. Faresti. described below. in thal they bolh have low. heasy, plangers loraled distally on finger wilh a heary sockel that is entirely open distally: the two species even carry the dactylus at aboul 90 angle to the vertieal plane of the body. Yed 1. compressus is withoul pahmar soulpure and is apparently relaled to the brevirostris deoup while 1. Foresti has unique and heary souphuring whidh
 found in the ednemedsii (iroup. This paralled development sungeste it may be in response lo some partirular mionmental repuirement, bul what that may be, as will the parallel body compression between 1. compressus and the coral symbionts mentimed. is beyond peredation al present.

The soure of the name is abvious. The hololype and paral ype from 81.30 and 71 will be placed in 1 he Musemm National dollistore Nalurelle: the paratspe from the fisheries Researeh station in Hong kinge * will be plated in the smilhsmian Instilutime
subsequent to the preparation of the above descriplion and diseussion wr have ohtameal one addilional specimen. a ? ? mon fromale lackine lar

## Discussion

Nost of the parat ypic series are hatking their laree chela and only a few haree chelane are lome in the jars. While these all stow the sentpuring of the patm of the holotype, in sume the ridues and erooves are less promounced, and in some the lingers are Gonger and may rarry stronger teeth al the lip: the plomer mas be localed eloser lon the middle of the dactylus. din intart femate of malure size bat mot ovigerous; has the same proportions and souphuring of the cheta as that of the mate latolype no the differences are not sexual.
 He genus. We have interpreted this soulpturing as derived from thal found in the edemedsii dironp.

* will the superior saddle or eroose hemes atmost vestigial and marked ly the persialand proximat
shoulder. The normal trimgular or quadramgular depresion on the superior purtion of the outer late. which in some species may extend proximally alonge the lemgth of the patm. hat become the marked longitudinal groose and depression extending almose to the cappal arlirulation: the medial superion depression. nomally conneeded with the transverse growe, has lost that rombedion and has hecome the ill-delimed bomiludinal depression. The inferior aroose and proximal shoulder persist as the proximal inferior groove. but do not extemb into a well-delined depresion on the lateral face of the palm, while the normally slight mid-palmar depression of the outer face behind the dactylar articulation is greally exageramed and conlinues in a disto-interior direetion to produce the distal inferior shoulder that demarks the end of the pollex. The displacement of the heasy phanger of the darlytus lo berond the middle of the arlicle and the greal thickening of most of the walls of the sockel of the pollex again are unique.

We do mol know how to interper the probable extension of the antero-medial lobe of the eyestalk beyomd the anterior marwin of the rarapare see fig. Ab, Infort mately this species is rather soft bodied and the dredping process has hadly distorted and infured mos of the sperimens: in some for example. Whe eyes and the bases of the andennate have heen entirely displaced and are hanging oul of the ratapace. However. in most specimens that are reanomatly intand the ocular process is exposed ats il is in the holotype. In one or two sperimens the proceso is entirely covered by the amapare. but in these the bases of the amtemmules appear lo be displaced dorsally. We helieve. therefore, that the condition of the hologye is the comdilion found in life. Derlapo the same development may be characLeristic of the olher new speries. 1. comperstes but the fome specimens of that speries are even more dislorted.

The presper of this prominence, al times developed into a spine has been noled by Coltame in his thesis 18 set: 111 m seg: in his ligures il is usually labeled epe $(-$ éping combenne? when il has a spinous erow (h): he sugees that it may be proterlive. In this rase the structure looks more sement. reperially its growh of hairs. This sperges lives in deep waler whew lille lighl nomatly penetrates. amd on a muddy hollom: it in possible that whem the comditions in the surmomding emviromment limil the vision of the well-developed eyes. hais secomdary sensory struclure may abl. However. 1. dillosus Oliviert. Habl lives deep in coral heads and has pesibly non-lumetional eye dheir color is pink and the orbitial hoods are covimed with spines: has no comparabla proceso.

Other species in the admardsii (iroul have some
rharacleristics in rommon with this species: for example both A. bisincisus De Itan and A. prosenchirus De Man have dorsally flallened rostrams with concave margins werlanging the flow of the orhitorostral groove ats do some members of of her groups. and some mud-dwellers. such as . 1. puphrosigne be Man and .1. malaburicus matabaricus Frabrivius and its various subsperies. have thattened datyli. hut no speries of the group show any lembancy lowad the development found in this targe rhelio. We are at lose to sugges any phyletie relatimship.

One further mole an be givern on this spectes: in one sperimen in which the rarapare was torn away. the contents of the thin-walled cardiare stomach could be seen. Mos of the contents apprared to be pireses of sand ome pieree. in lack. Was hark and hooked like an irregular hasallia grain hat other objeets were detinitely fomminiferans of varions genema

This speries is mames in homor of lor. . facques
 ion. the collechor of there specimens and a leflow rarcinologist when has been most helptul in war studies. The hololype and paralymes will be placed in the Musem Nalional dolishoire Xaturelle, Paris.

## REMARKS

These specimens agree well with the origimal 6 speciment that Hi Mas described from Indonesia. De: Man did mol have a small male dheliped so we
 The smatl chela is sexually dimorphie. the male having the lypical balateniceps condilion. Chelat 1.7 limes as long as hroad wilh lingers and palm nearly equal in lemoth. Superior margin of palm bearing a transverse small eroose prosimal to dactylus wilh proximal edge of groove continumg as small, poorly-defined superior ares disappearing about middle of chela. Chela besed wilh sparse time selae. Merus $2 . f$ times as long an broad. superndistal margin inermous, infero-internal marein bearing fine, sparse selate and an arute tooth distally.

- Merus of third leg 7 times as lome as hroad in male * and nearly 10 times in female.
- DE: Mives specimens from Indonesia came from
 $9(13-1311$.

Having found these specimens so like the desraptions and ligures of De Max. we question the identificalion of the sperimen we reported under this name from the dialf of Thailand 13.8 B B. I 1966 : 126 . lig. 17 from mud at 60 m . In that specimen, a male of lis mom. The small rhela was more slender will lingers of different shape, and the dactylus of the fourth leg was simple thied leg was losit). I'nlortumalely, the specimen was destroyed by fire

Alpheus pustulosus Banner and Banner (lig. : i)

## Material

1 sperimen from si. int.

## Remarks

This 1? mon malde compares favorably with the lype. which we have reexamined, with the exception that the chelipeds are more slender. The large chela is St limes as long as broad instead of 4 limes and the smatl chela is x. $x$ limes as long as broad instead of 7.x. The meri of both chelae are over 1.0 time an lone as hroad inslead of :3.5. With no lew specimens known. We are not al preaent attaching any signiticance to these varialions.

In our original descriphion we failed lo remark upon or figure the third maxillipeds. In the holotype. like this speremen. the ration of the artieles is 10 : $:$ : 6 . The supero-evemal margin of the first article leminates in a strong acute looth while the superor internal margin terminates in a small rounded tooth. The tip of the third article bears a brush of longe hairs. The acule toolh on the lip ol the basal article is unusual in the brevirestris diroup.

The only previous record of this species was that of the holotype dredged near llong Kong

## Alpheus spatulatus Banner and Banner

## Material.

1 sperimen from il. 7 .

## Remarks

The only previous recond is that of the holotype and paratypes laken from 75-9. an in the south China seat south and west of Hong kong. These specimens were taken al $122-1 \cdot 2 \mathrm{~m}$.
